*** Important note: all the data here is purely fictional and has no relation with any real data.**

Executive Summary

This report presents a comprehensive analysis of Uber ride activity across four European markets — Poland, Austria, Czechia, and Germany — throughout 2024. Using a robust star schema dimensional model built in Power BI, the analysis explores key performance drivers across Rides, Drivers, Customers, and Trends, based on approximately 10,000 rides.

Key Findings

Rides & Revenue: Poland recorded the highest number of rides, while Germany led in total revenue due to significantly higher average ride value. Czechia showed the weakest performance in both volume and market penetration despite a competitive average fare.

Payment Behavior: Bank Transfer and Cash dominate (~70% of rides with known methods), while nearly one-third of transactions lack payment information — a major data quality concern that hinders modernization efforts toward digital wallets.

Driver Performance: The average driver rating stands at 3.96 (below the internal target of 4.5). More concerning is the driver base composition, with only one-third of drivers Active and approximately two-thirds either Inactive or Suspended. Earnings are heavily concentrated in the €10K–€30K range, suggesting many drivers treat Uber as a side hustle.

Cancellations: The overall cancellation rate is high at approximately 38.5%. Driver cancellations (1,816) significantly outnumber customer cancellations (724), with “Personal Reason” and “Vehicle Breakdown” as the leading causes.

Customer Base: Customers are relatively well balanced across the four countries, with Germany showing a slight edge. Platinum members are the most numerous, though Standard members demonstrate the highest average spend.

Temporal Trends: Activity peaked in July, with the single busiest day occurring on Tuesday, 22 October 2024. Ride volume shows clear daily peaks between 17:00–19:00, consistent with typical commuting and evening travel patterns.

Main Challenges & Opportunities

The business faces notable challenges in driver retention, high cancellation rates, and payment data quality. However, strong performance in Germany and Austria, combined with a solid customer foundation, provides a good platform for growth — particularly through targeted actions in underperforming markets like Czechia and operational improvements to reduce cancellations and reactivate drivers.

This analysis highlights clear opportunities to increase revenue per ride, improve driver engagement, and enhance data quality, which together could significantly strengthen Uber’s position in these Central European markets.

Presentation

This model aims to make an analysis of Uber rides, in some specific European Countries (Poland, Austria, Czechia and Germany) during the year of 2024.

To achieve that, a relational model was created, as per the image below. The model consists of a fact table (Fact_Rides) and six dimension tables (Dim_Booking, Dim_Customer, Dim_Date, Dim_Driver, Dim_Location, Dim_Vehicle), with the respective columns on display:

Figure 1 - Relational model, tables and columns

The fact table pretends to include mostly quantitative measurements (essential for the analysis) plus the foreign keys that allow to connect it with the other tables.

As per their own definition, the dimension tables exist here to give context and additional information to what the fact table is measuring. The logic behind these dimension tables, relies on what is essential in any uber ride: the vehicle, the driver, the customer, the reservation (booking), plus two other dimension essential for a richer context of each ride – the location and the date.

The analysis is divided in three main categories: rides, drivers, customers and trends.

Rides

In this category, the objective is to give a general overview of the rides.

We start by doing a country-based analysis of the total value of the rides and the total number of rides, as per the images below:

Figure 2 - Total Rides by Country

Figure 3 - Total value of the rides by country

If Poland is the country with the most rides in our database, when analysing the total value of the rides, the first place is taken by Germany, and Poland appears only at 3rd place.

To search for the reasons behind this difference, a new visualization was made: the average value of each ride per country.

Figure 4 - Average Value of Rides by Country

The average value of each ride in Poland was not only below the value of Germany, but it was also the lowest value among the 4 countries. That was the main reason that explains that difference.

Another insight was spotted on the first two figures. Despite having similar populations, Austria is the second country with the highest total value of rides and total number of rides, and Czechia is in the last position. Even with Czechia having the second highest average value of rides.

Management should investigate penetration strategies in Czechia to be taken from this analysis, is to try to understand why the company has the lowest penetration in Czechia, compared with the other 3 countries, since Czechia was even the country with the total number of rides below 9 thousand.

Making an analysis of the TOP 10 cities by number of rides, we can see that the first places are cities in Poland and Austria, with the first German city (Berlin) in 5th place, and no Czech city on the TOP, as we can confirm on the image below.

TOP 10 Total Rides by City

Figure 5 - 10 cities with the most rides

Moving to the method types, it's possible to see on the image below that the main method type was Bank Transfer, with almost 42%.

Figure 6 - Distribution of the payment methods

Together with cash, the second most common payment method, they represent almost 70% of total rides.

This raises some questions, since they are two payment methods that are considered more *old school*, slower and less practical, if compared with the other three: uber wallet, credit and debit cards. This raised the need for some work on trying to modernize the payment system.

However, it's also worth to mention that there are almost 3.700 transactions that didn't have any payment method registered. This represents approximately one third of the total rides. This is a major red flag for data quality, negatively affecting the goal of modernization mentioned above. It is necessary to make a more detailed investigation for the reasons behind these values.

If the payment methods on these transactions were mainly from the other three categories, having those numbers would have changed output and the analysis. However, nothing can be concluded with certainty related to this topic.

Drivers

Regarding the analysis of the drivers, the first data in the dashboard is the average of the rating for all the drivers. With a scale from 1 to 5, the average was 3.96, close to 4.

Figure 7 - Average Rating of all drivers

The team in charge of managing the drivers work and performance, defined a target of 4.5 for the average rating. As the image below shows, the value is below that target.

Figure 8 - Driver Average Rating Performance

The first chart in the report (in the image below) shows the total number of drivers by status and the weight of each category in the total number of drivers.

Figure 9 - Total number of drivers by Status

It's important to note that the values are all very similar, with a slight majority of drivers with a "Suspended" status.

Without further data, it's not possible to obtain a deeper understanding of this situation. It would have been necessary to get the information about the reasons for the suspension of the drivers, to be able to take more insights from that, and to take some actions.

According to Uber's internal policies, if a driver wants to stop offering their services in the platform, their account (after internal checking by the responsible team to investigate if everything is in order with the driver's account) goes immediately to the "inactive" status.

If there's any report associated with the driver's account or activity, for any of the reasons described in the code of conduct, the account is switched to "Suspended" status until the final decision from the analysis of the case is taken. In this case the driver's account can return to the "active" status or go to "inactive" as well.

Since the reports can be performed either by the internal team, but also by any of the driver's customers, these circumstances can greatly explain the values for "suspended".

However, this situation will require a further analysis, after the release of this report, by the team in charge of this.

If we consider the number "suspended" and "inactive" together, they account for approximately 2/3 of the total number of drivers registered in the dataset. That obviously means that only 1/3 of the drivers are actually active, which is a concerning situation.

Another aspect raised by the team was if there was any possible relation between the status of the driver and their rating. That would mean, if the drivers in the “Suspended” group would have a lower rating, since the drivers that receive a report against their work would be moved to this category.

However, as seen by the table below, the average rating in each status group is very similar, and the “Suspended” group reached the higher value, the complete opposite of the initial idea.

Status	Average Rating
Suspended	3.97
Active	3.96
Inactive	3.95

Figure 10 - Average Rating by Status

The image below replicates a histogram analysis of the distribution of the number of drivers on each earnings range (band).

Figure 11 - Statistical distribution of earnings

To obtain this visualization an extra column was added to the Dim_Customer table, adding each earning to one of the bands that were defined as per the image.

We can see from the graphic that the majority of the drivers are in the 10K-20K range, followed by the 20K-30K and the lowest range (<10K). The highest ranges (>40K) have the lowest number of drivers.

This chart triggers some actions that need to be taken. Although a significant proportion of the drivers are using this service as a side hustle/part-time (data not included in this dataset, but included on others), it is for the best interest of the company and the drivers, that they can maximize their earnings. Something like that would motivate the drivers to keep working with Uber and possibly could attract new drivers. These values can also partially explain the high number of “inactive” drivers in the database (drivers who stop offering their services, since they found out that it wasn’t meeting their financial expectations). Linked to that, it’s important to make a deeper analysis of this situation and try to find feasible and realistic solutions to improve this scenario.

Analysing now the reasons for cancellations, from the driver’s perspective, the table below shows that there were 1816 cases of cancellations by drivers (roughly 18% of the total rides).

Reason Cancellation Driver	Total of Observations
Personal Reason	388
Vehicle Breakdown	369
Passenger No-show	359
Emergency	352
Traffic Congestion	348
Total	1816

Figure 12 - Total of cancellations from the driver by reason

The main reason was “Personal Reason” with 388, followed by “Vehicle Breakdown” with 369, and “Passenger No-Show” with 359.

Analysing these reasons, it’s possible to understand that none of these reasons is related with something that the company could have handle in order to reduce the occurrences.

The last visualization included in this category was the number of total rides by type of vehicle.

Total Rides by Type of Vehicle

Figure 13 - Total Rides by Type of Vehicle

The most common vehicle is a “Premier Sedan” with 128 thousand rides, followed by Go Mini (124 thousand) and “Bike” (121 thousand).

Below the mark of 100 thousand rides, we have only “Uber XL” and “Auto”.

The last element added in this category was an automation to send a summary, that triggers an email with current KPIs to a predefined address, that was done through a power automate flow.

After the button is triggered, an automatic email like the one below would be sent to the email addresses included in the mail list.

Figure 14 - Automatic email sent after the automation is triggered

Customers

The last category of this analysis is about the Customers.

Starting by the distribution of customers by country in the image below, it's possible to conclude that the number of customers is equally distributed among the 4 markets, with the leading for Germany – having 25.8% of total customers, but with all the markets getting a percentage of all the customers between 24.5% and 25.8%.

Figure 15 - Distribution of Customers by country

Making now a geographic analysis by city, the distribution of customers by city of origin, confirms the dominance of Germany, since Berlin is at the first place, as can be seen on the visualization below.

Figure 16 - Distribution of Customers by City

If the average rating of the drivers was below 4 (on a scale 1 to 5), the average of rating given is better, with an average value of 4.25.

Figure 17 - Average Rating Given by all customers

Another question that was raised related with the Rating Given was, if the seniority of the customer using this service, would have any influence on the rating given by the customer.

However, the scatter plot below shows that there's no real relation between customer seniority and average rating given by the customer.

Figure 18 - Relation between Average of Rating Given and Customer Seniority

Analysing now the Customers by membership status, the first place was taken by the “Platinum” status with approximately 2.6 thousand, but followed very closed by the other three status, all of them with around 2.5 thousand.

Figure 19 - Customers by membership status

Inside the membership status topic, another visualization was built, this one about the average spent by membership status, as per the image below.

Figure 20 - Average of Total Spent by Membership Status

Despite being the status with the most members, when regarding the average of total spent, “platinum” only appears on the 3rd place, with 1877. The first place is taken by “Standard” with 1922, when it was in the second place on the previous visualization.

“Silver” appears on the last place on both charts.

Making now an analysis of the reasons for cancellation, but this time on the customers’ side, the first thing to be highlighted, is the fact that the total of the observations with a reason for cancellation done by a Customer, is less than half of the observations on the drivers side (724 on this case against 1816).

Reason for Cancellation Customer	Total of observations
Wrong Pickup	163
Found Alternative	151
Long Wait Time	143
Driver Too Far	135
Change of Plans	132
Total	724

Figure 21 - Total of cancellations from the Customer by reason

Moving for a deeper analysis of the reasons, the main reason was “wrong pickup” with 163 observations, followed by “Found Alternative” with 151 and Long Wait Time with 143.

Finally, the last element of this category is another Power Automate resource, that sends an automatic email when one of the reasons for cancellation achieves a concerning level, that will need attention and adequate action.

After the button is triggered, an automatic email like the one below would be sent to the email addresses included in the mail list

Figure 22 - Automatic email sent after the automation is triggered

Trends

The last chapter of the analysis, focus on the analysis over the time frame of the dataset: a trends analysis.

Starting by an analysis on month-level, these two visualizations show the total rides and the total cancellations by month.

Figure 23 - Total rides by month

Total Cancellations by Month

Figure 24 - Total Cancellations by Month

It's possible to conclude that ride volume and cancellations followed a similar monthly pattern. July was the busiest month by a clear margin, followed by March and October, while November recorded the lowest activity.

This distribution does not reveal a strong, easily explainable seasonal pattern. One possible hypothesis is that July benefited from summer tourism and holiday travel in Central Europe, while the lower activity in November may be related to post-summer slowdown and pre-holiday caution. However, with only one year of data, it is difficult to distinguish between seasonal effects, marketing campaigns, or external events.

The significant peak in July suggests there is clear demand that can be stimulated. Management should investigate the drivers behind July's performance (pricing, marketing, fleet availability, or events) and attempt to replicate successful conditions in weaker months. Additionally, the consistently high cancellation rate across all months remains a priority area for operational improvement.

Even though July was the month with more observations, with a comfortable margin over the 2nd and 3rd places, the busiest day of the year was actually in October: the 22nd, as per the card below.

Tuesday, 22 October 2024

Busiest Day

Figure 25 - Busiest day of the year

To obtain this date, a measure was created, with three variables – “SummaryTable”, “MaxRides” and “BusiestDate” – where the Busiest day expressed an operation between “SummaryTable” and “MaxRides”.

Moving now to a quarter analysis, the following image shows the total cancellations and completed rides by quarter.

Figure 26 - Total Cancellations and Completed Rides by Quarter

It's possible to see that the number of completed rides was always significantly lower than the number of cancellations, and both variables showed the same pattern through the quarters.

The quarter with more observations was the first one (January – March) and the fourth was the one with less observations (October – December).

This comparison raised concerns for the decision-makers, as no successful company wants to have way more cancellations than completed actions, no matter the sector is.

The reasons for cancellations, from both driver and customer sides, were already presented and analysed before. Although the conclusion was that none of the reasons was for something that could have been done differently from the company, it is still very relevant to try to find ways to reduce the high number of cancellations.

The last visualization, as presented in the next figure, was the total rides per hour.

Figure 27 - Total Rides by Hour

From the line chart, it's possible to conclude that the peak of activity was between 17h and 19h, followed by 10h, with the lowest activity being between 21h and 5h in the morning.

This pattern coincides with the typical behaviour of this activity, since it's during the night that less people are travelling, and the busiest hours are in the late afternoon/evening, when people are leaving from their activities (work, studies) and going to other appointments.

Conclusions and recommendations

This analysis provided several reasons for action, since some points of concerning were identified.

Starting by the analysed markets, it is important now to find ways to increase the activity in Czechia, since this country presents values considerably below the other three countries. One of the recommendations is to conduct a focused marketing and operational review to understand barriers to growth and replicate successful strategies from Germany and Austria.

Related with the Payment Methods, as it was mentioned on that section, the number of observations that didn't have the payment method associated was a quality concern. It is important to investigate the root cause of why those observations remained empty. Moreover, the biggest concern here is the fact that the most used payment methods were "Bank Transfer" and "Cash", and the most practical and modern methods are very underrepresented. Some urgent attention is needed to change this situation.

From the drivers' analysis, the first main concern, was the fact that the average rating of all the drivers is still below the benchmark.

However, the biggest red flag here was the big percentage of drivers that are currently not active in the database. As it was mentioned during that part of the report, although the reasons for a driver to become "suspended" or "inactive" are well known, the need to try to understand why so

many drivers leave the service by their own will, or how many that are moved to “suspended” due to some reports, don’t return to “active”, remains. More information should be collected in order to design a plan to reverse the current scenario.

Related to the high level of cancellations, the recommendation is to analyse peak cancellation hours and locations, to be able to implement operational improvements to lower the cancellation rate.
